You learned in chapter 2 that we change our point of view when we move from a container runtime like Docker to an orchestration platform like Kubernetes. With Docker, we deploy containers to an individual machine. With Kubernetes, we deploy containers to a cluster of machines, enabling scalability and resilience.

Kubernetes clients use an API to interact with the Kubernetes Control Plane, which is responsible for creating and managing objects in a Kubernetes cluster. In this new scenario, we still send commands to a single entity, but it acts on several machines rather than only one. Figure 7.2 shows the logical infrastructure when we use Kubernetes.
