`/monitor` endpoint that can trigger a configuration change event in Config Service, which then would send it over the Bus to all the listening applications. It also accepts arguments describing which files have been changed and supports receiving push notifications from the most common code repository providers like GitHub, GitLab, and Bitbucket. You can set up a webhook in those services to automatically send a `POST` request to Config Service after each new push to the config repo.

Spring Cloud Bus solves the problem of broadcasting a configuration change event to all connected applications. With Spring Cloud Config Monitor, we can further automate the refresh and make it happen after a configuration change is pushed to the repository backing the config server. This solution is illustrated in figure 14.1.
