When a ConfigMap is mounted as a volume to a container, it generates two possible outcomes (figure 14.2):

- If the ConfigMap includes an *embedded property file*, mounting it as a volume results in the property file being created in the mounted path. Spring Boot automatically finds and includes any property files located in a `/config` folder either in the same root as the application executable or in a subdirectory, so it's the perfect path for mounting a ConfigMap. You can also specify additional locations to search for property files via the `spring.config.additional-location=<path>` configuration property.
- If the ConfigMap includes *key/value pairs*, mounting it as a volume results in a *config tree* being created in the mounted path. For each key/value pair, a file is created, named like the key and containing the value. Spring Boot supports reading configuration properties from a config tree. You can specify where the config tree should be loaded from via the `spring.config.import=configtree:<path>` property.
