4.3 Develop the smart contract

To get you started quickly with the Dapp design process, we'll reuse the balloting problem introduced in chapter 3. The problem statement is repeated here for your convenience.

> **PROBLEM STATEMENT** Consider an online ballot application. People vote to choose a proposal from a set of proposals. A chairperson registers the people who can vote, and only registered voters can vote (only once) on a proposal of their choice. The chairperson's vote is weighted twice (x2) as heavily as regular people's votes. The ballot process goes through four states (`Init`, `Regs`, `Vote`, `Done`), and the respective operations (initialize, register, vote, count votes) can be performed only in the corresponding states.
