Listing 4.3 Deploy script for Ballot smart contract (2_deploy_contracts.js)

```
var Ballot = artifacts.require("Ballot");      ❶

module.exports = function(deployer) {
  deployer.deploy(Ballot,4);                   ❷
};
```

❶ Specify the contract to be deployed.

❷ Ballot constructor is sent a parameter (4) for number of proposals

The 2_deploy_contract.js file specifies the contracts to deploy and also the parameters to the constructor, if any. In this case, the parameter to the Ballot's constructor is initialized to 4, meaning that there are four proposals to vote on. You can deploy any number of contracts with this script; at this time, you only have the Ballot contract, but you can configure 2_deploy_contracts.js to deploy other smart contracts as you develop them. You'll see one additional file, 1_initial_migration.js, in the migrations directory; this is the script for deploying the initial migration, Migrations.sol, which is required by `truffle migrate`. The prefixes 1 and 2 in the names stand for the migration steps, 1 and 2. Do not change the filenames.

Navigate to the root of the ballot-contract directory (ballot-contract). Make sure that the Ganache chain is launched and ready (section 4.2). Type the following command to deploy your Ballot contract on the Ganache test chain:

```
truffle migrate –-reset
```
