4.4.5 Connect web client to smart contract

One more piece of code is important for Dapp development: the piece that connects the web app to the smart contract. Recall from our discussion of the directory structure in section 4.4.1 that app.js is the glue that connects the web client to the smart contract through a set of handler functions. This code provisions the web3 and smart contract services for the web front end to call and invoke. The next listing shows the headers of the function scripts of app.js.

Listing 4.6 Glue code between UI and smart contract via web3 API (app.js)

```
App = {
  url: 'http://127.0.0.1:7545',                    ❶

  init: function() {                               ❷
    return App.initWeb3();
  },

  initWeb3: function() {                           ❸
                                                   ❸
      App.web3Provider = web3.currentProvider;     ❸

    return App.initContract();
  },

  initContract: function() {                       ❹

    App.contracts.vote.setProvider(App.web3Provider);
    getJSON('Ballot.json', function(data) {

    return App.bindEvents();

  },

  bindEvents: function() {                         ❺
    $(document).on('click', '.btn-vote', App.handleVote);
```
