entities in the MPC-Dapp. Figure 7.11 shows the sequence diagram with four interacting entities: the organizer, the smart contract, the worker, and the verifier.

Follow the diagram from top to bottom along the timeline. The organizer account deploys the MPC smart contract with the two addresses that are participants in the micropayment channel: the address of the sender-organizer and the address of the receiver-worker. This action opens the channel for off-line micropayments. The worker collects the plastics garbage in bins and delivers it to a verifier. The verifier could be an automatic machine that validates the contents of the bins and sends the data about the bins collected to the organizer. Every time this data arrives, the organizer sends an equivalent micropayment (off-chain data) for the work performed to the worker. This cycle is repeated until the worker decides to call it a day. They send the `claimPayment()` request to the MPC contract with the amount (in the latest message) and the signed message. The smart contract verifies it and pays the worker. After the payment is confirmed, the MPC smart contract is undeployed, by which action the channel is closed.
