function is a voting smart contract. The functions are `validateVoter()`, `vote()`, `count()`, and `declareWinner()`. The invocation of these functions results in the transactions that will be recorded on the blockchain (`Tx(validateVoter)`, `Tx(vote)`, and so on). This ability to deploy an arbitrary logic on a blockchain significantly enhances its applicability beyond simple cryptocurrency transfers.

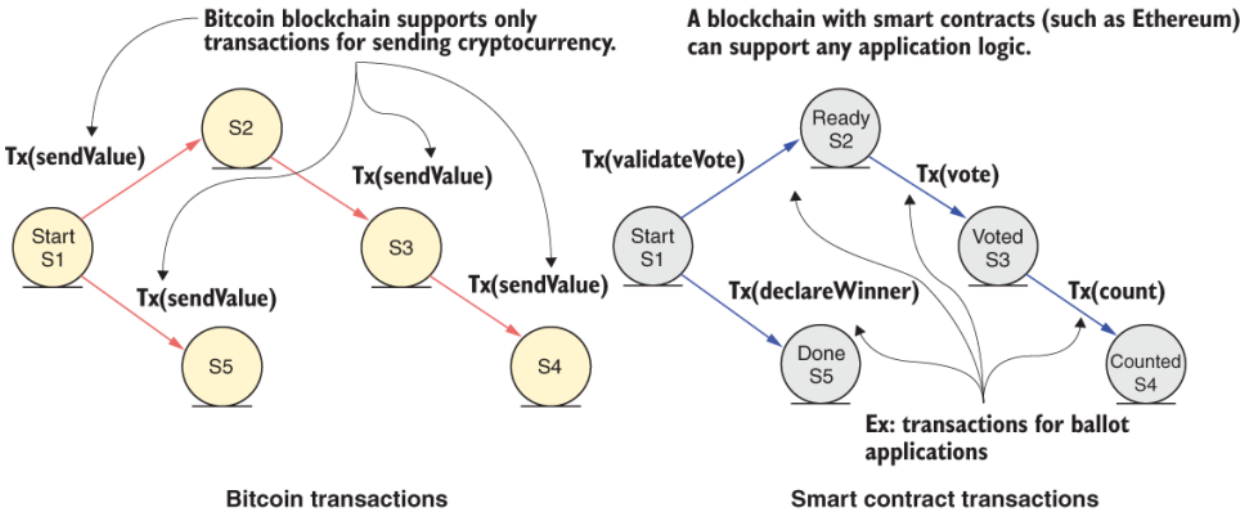

Figure 2.2 Cryptocurrency transactions versus smart contract transactions

2.1.2 What does a smart contract do?

The smart contract acts as the brain of a blockchain application. Like the human brain, it is responsible for many vital functions, including the following:

- It represents a business logic layer for verification and validation of application-specific conditions.
