

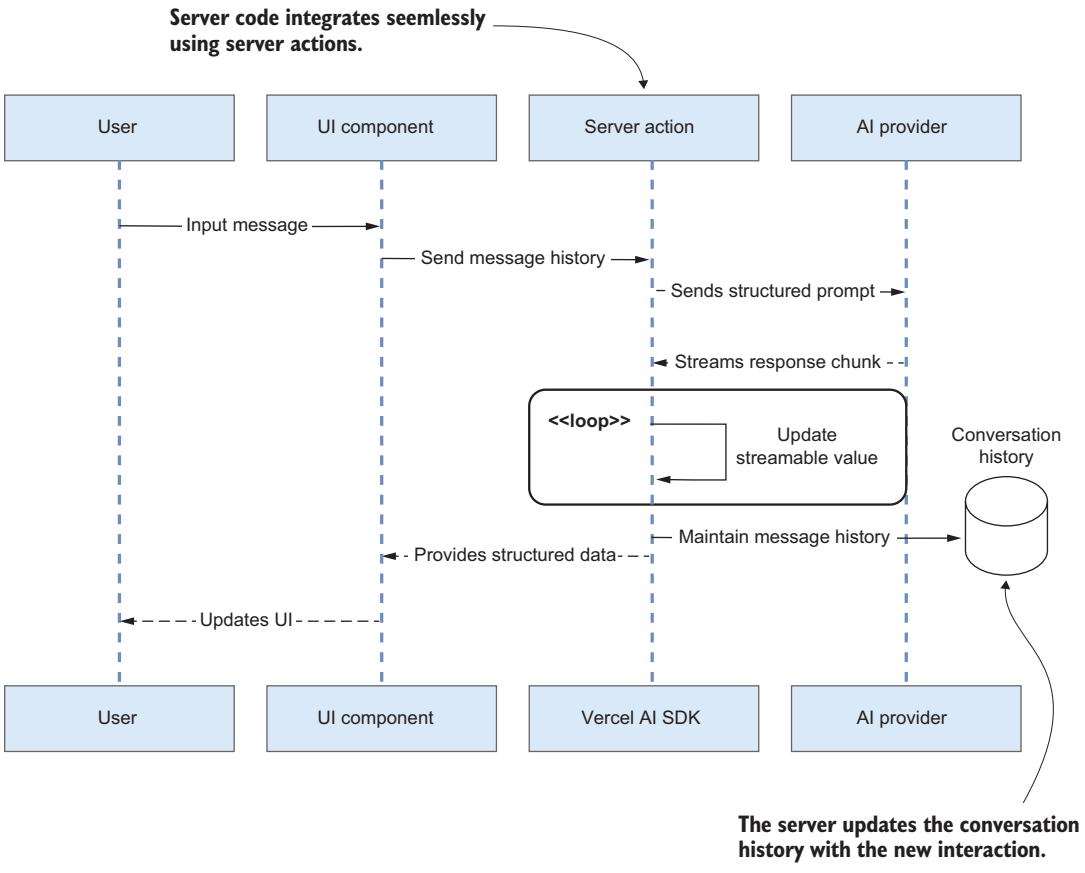

Figure 4.4 React server actions in action. User input travels from the prompt to the AI provider. The response is streamed back in chunks, updating the client in real time while maintaining the conversation state in memory.

Listing 4.1 Server action that creates a streamable conversation

The 'use server' directive indicates that this code should only run on the server, enabling server actions.

Imports necessary functions from the Vercel AI SDK, including createStreamableValue, which is specific to RSCs. This function returns a value that can be used to stream data back to the client.

Creates a streamable value that can be updated incrementally and sent to the client in real time

```
'use server';
import { streamText } from 'ai';
import { createStreamableValue } from 'ai/rsc';

export async function
continueConversation(history, provider, model) {
  'use server';
  const supportedModel = getSupportedModel(provider, model);
  const stream = createStreamableValue();
  (async () => {
    const { textStream } = await streamText({
```
