

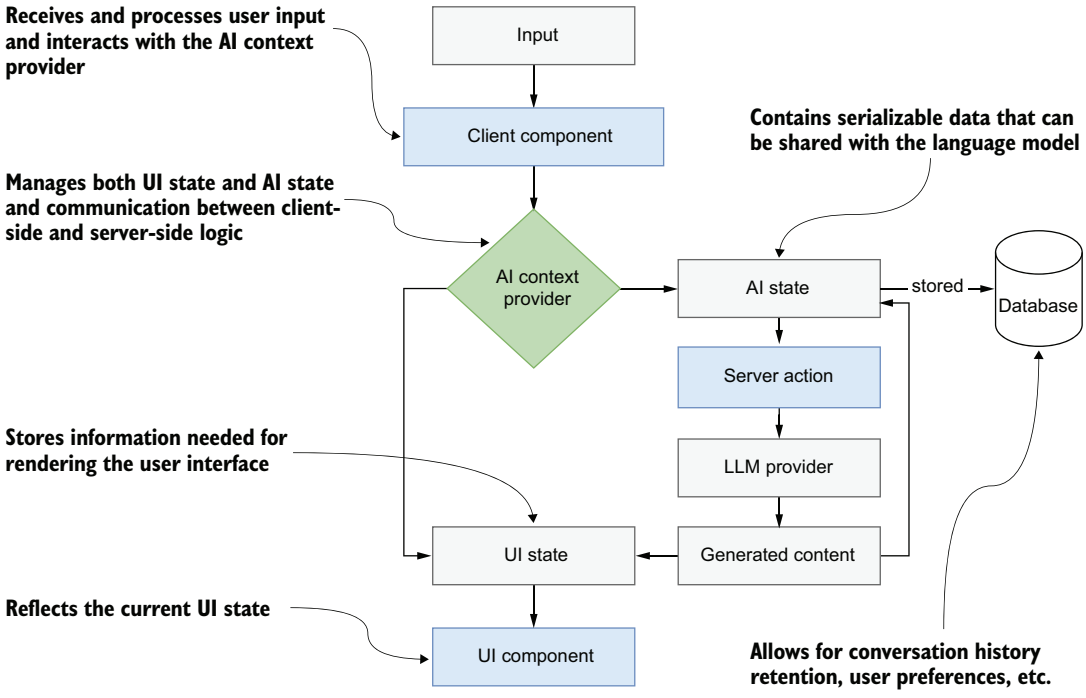

Figure 4.8 AI and UI state representation. Once the user submits a prompt, it goes through a pipeline of events and actions for the final output to be consistent.

can be stored in a database. UI state is used to render the interface, which then accepts new user input.

AI STATE

AI state represents the serializable data that can be shared with the language model and used on the server. It typically includes the following pieces of data:

- Conversation history: messages between user and assistant
- Metadata: for example, timestamps, conversation IDs
- JSON representations of generated components

These kinds of data would almost not be needed in the UI, so there is no need to share them with every conversation thread to the client. They need to be kept in a separate context.

UI STATE

UI state, on the other hand, is a client-side state that encompasses the actual rendered elements and React components. It typically includes components rendered with state parameters:

- *React elements and components*—For instance, `<Button isDisabled={true}>` or `<Input value="hello" />`
