searches. This approach enables us to efficiently retrieve relevant information based on user queries. Let's explore the process in more detail step by step.

STORING AND RETRIEVING WITH EMBEDDINGS

In the general case, we aim to develop a system that generates a list of embedding values based on the body of knowledge we want to serve. Once this knowledge is embedded, when a user submits a query, the system can compile a list of similar queries or relevant recommendations that align with the original query. This functionality can then be integrated into our web application, enabling us to display the results in an intuitive and user-friendly manner. Figure 5.10 showcases the general steps involved in this process.

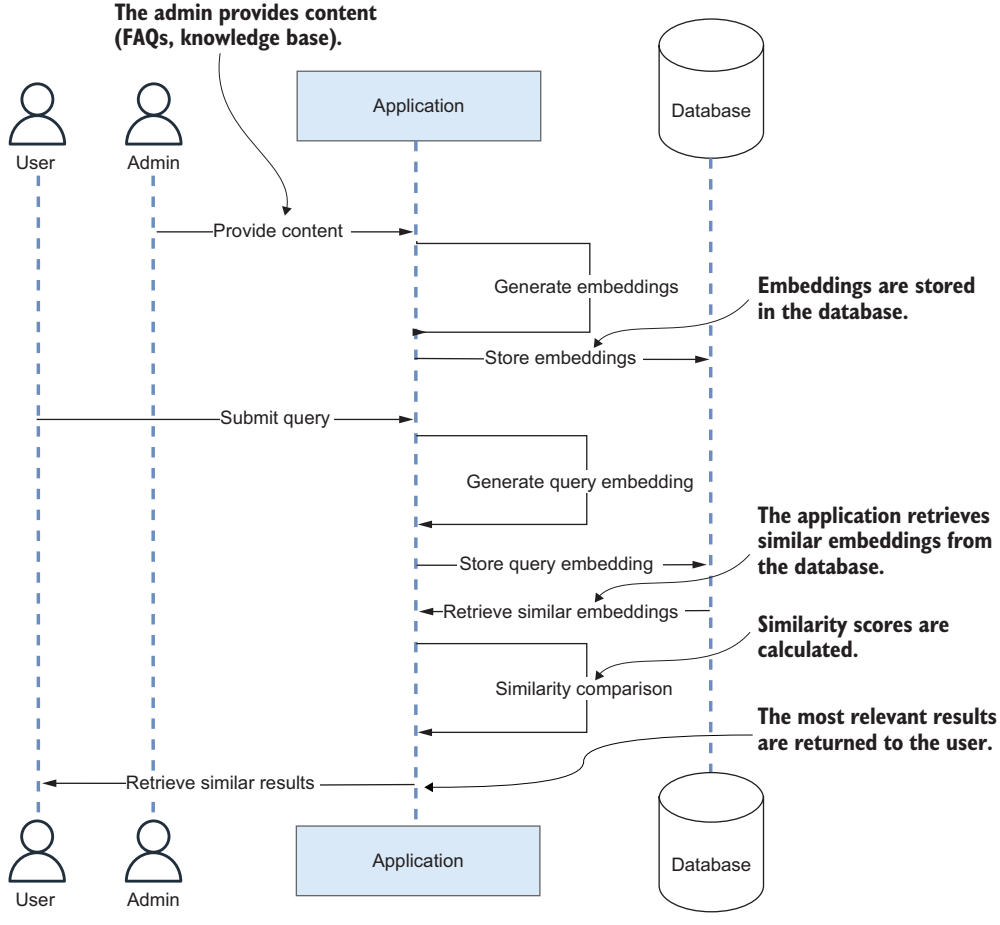

Figure 5.10 The workflow of an information retrieval system that utilizes embeddings to enhance user query responses. An admin provides content, such as common questions and knowledge base articles, to the application, which generates embeddings for this content and stores them in a database. When a user submits a query, the application generates a corresponding query embedding and stores it as well. The system then retrieves similar embeddings from the database and calculates similarity scores to identify the most relevant results. Finally, these results are returned to the user.
