Now start the application and try to ask a few trivia questions. You will see that the response format matches the prompt instructions we required when we defined the prompt template. Figure 6.3 showcases an example interaction.

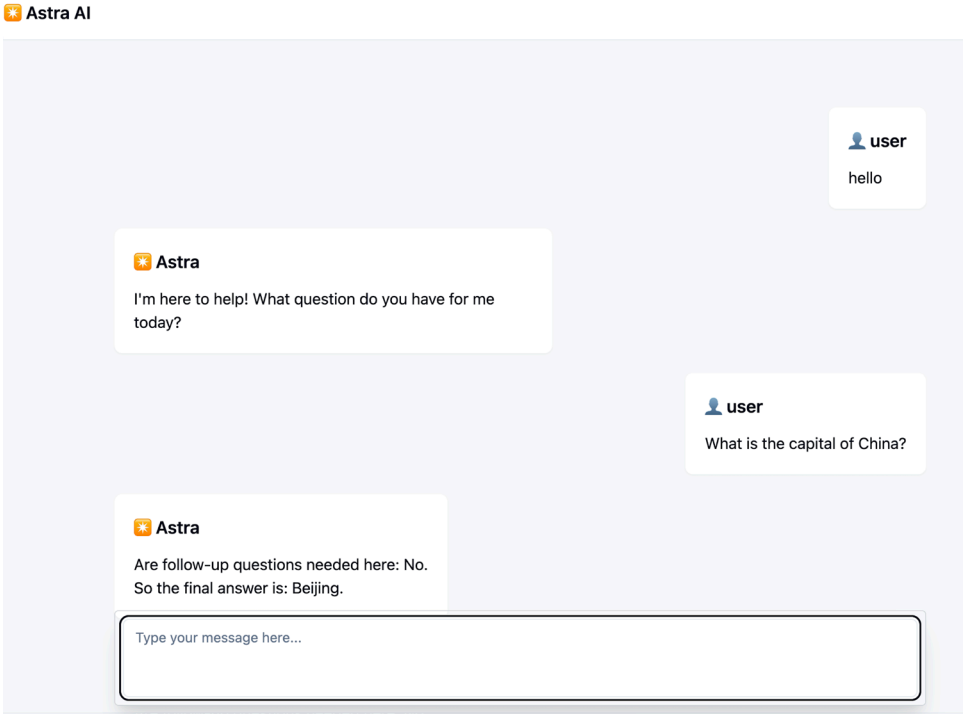

Figure 6.3 Sample interaction with our AI agent that formats the answers based on the examples provided. Behind the scenes, it utilized the `FewShotPromptTemplate` class from the LangChain.js project.

The main benefit of using a `PromptTemplate` is flexibility: if we need to change the style or tone or add more examples later, we can update the template in one place without refactoring the entire project. This makes the system more maintainable, easier to scale, and capable of producing higher-quality, more predictable responses.

Integrating chain calls

To integrate chain calls and stream the results back to the UI, it's important to note that we cannot currently use the `streamUI` function from the Vercel AI SDK in conjunction with the LangChain.js chain. This limitation arises because LangChain does not provide an adapter for the AI SDK's language model specification. Therefore, we need to separate these functionalities. So instead of using

```
import { google } from '@ai-sdk/google';
import { openai } from '@ai-sdk/openai;
```
