

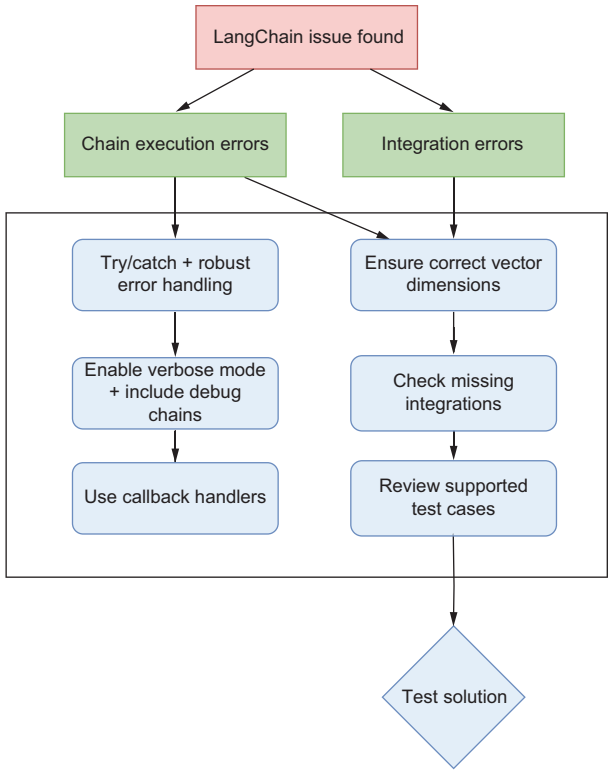

Figure 8.7 LangChain.js problems and their respective debugging and resolution steps

reliably, and testing potential solutions systematically. The more experience you gain from working with active services, the more efficient you will be at detecting and resolving production errors.

8.3.1 Chain execution errors

The most common error you will encounter when working with LangChain is chain execution errors. These occur when there's a problem in the flow of your chain execution.

Many things related to chain execution can significantly affect the reliability and performance of applications. One is undefined outputs, which often occur when required inputs are missing, leading to incomplete or erroneous results. Additionally, incorrect data propagation disrupts the flow of information between different components of the chain, resulting in unexpected behaviors. Finally, unexpected chain termination happens when unhandled errors occur during execution.

WRAPPING EXECUTION WITH TRY/CATCH STATEMENTS

One way to tackle potential errors, with respect to the way that you normally compose chains, is to wrap the execution chain into a try/catch statement. The following listing shows an example.
