

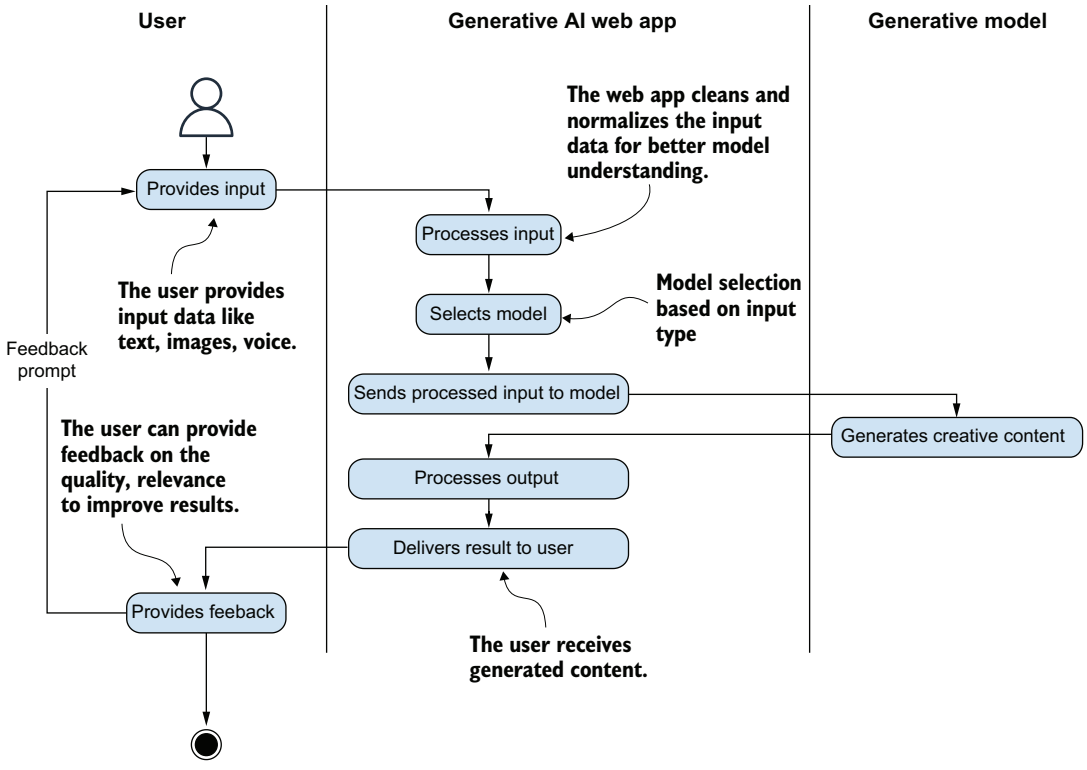

Figure 1.2 How an AI web app works: the user inputs data, and then the app processes it, selects a model, generates content, delivers it, and, optionally, collects feedback.

to this query and to improve the model's performance, thereby enhancing the quality of future responses.

At its core, a web application comprises a service hosted on the public internet. As you can see in figure 1.3, clients, whether web or mobile apps, can access the service to utilize its content and features. The service itself may encompass multiple components that communicate with other services on the public internet to deliver its features. While some services store state in a database system, others may remain stateless.

1.3 AI tools and the ecosystem

To build AI apps, we follow standard software engineering practices, using modern tooling to improve UI/UX, implementing effective testing and deployment strategies, securing APIs against potential threats, and optimizing performance through quality assurance. Let's look at some of these tools and platforms that can streamline the build process.

Many tools, services, and libraries streamline the build process, and this ecosystem continually evolves with new updates and features while striving to improve the accuracy of existing models. Many generative AI tools are available in both commercially
