- *Implementing a fact-checking tool*—You can instruct the AI to use tools based on the question type to perform fact verification. For example, you might cross-reference the extracted keywords against a knowledge base to verify accuracy and identify potential misconceptions.
- *Implementing a custom scoring system*—You might devise a scoring system that quantifies the candidate's performance in different areas (technical skills, communication, problem solving, etc.). This will make the feedback more objective and easier to understand.

Of course, the idea here is to provide the AI with the right amount of context and precise prompt instructions to deliver a valid and fair review of the candidate's performance. Using prompt engineering techniques, as discussed in chapter 5, and experimenting with a variety of configurations will significantly enhance the system's value.

10.4 Additional considerations and improvements

At this point, I urge you to try out the web application and see how it behaves. Here are some aspects to review and potential improvements:

- *Text-to-speech integration*—The application effectively uses text-to-speech functionality to provide audio feedback.
- *Feedback generation*—The feedback page offers comprehensive insights based on the interview session.

On the other hand, some pieces are missing, and these would be nice additions to the existing application:

- *Speech-to-text interactions*—Currently, users cannot interact with the AI using voice commands. Implementing speech-to-text functionality would allow users to speak to the AI agent, like how text-to-speech is used. You can reference examples like Google's Speech-to-Text API for inspiration.
- *Follow-up interviews/multiround interviews*—The feedback page could be enhanced to facilitate follow-up interviews based on previous feedback. This would help users track progress over time.
- *Graphical visualization*—Providing a graphical representation of technical performance points could make feedback more engaging and easier to understand. This could include charts or graphs to highlight areas of improvement.
- *Personalized practice plans*—Generating individual practice plans based on low performance points would offer users actionable steps to improve. This could involve AI-driven analysis to tailor recommendations.
