

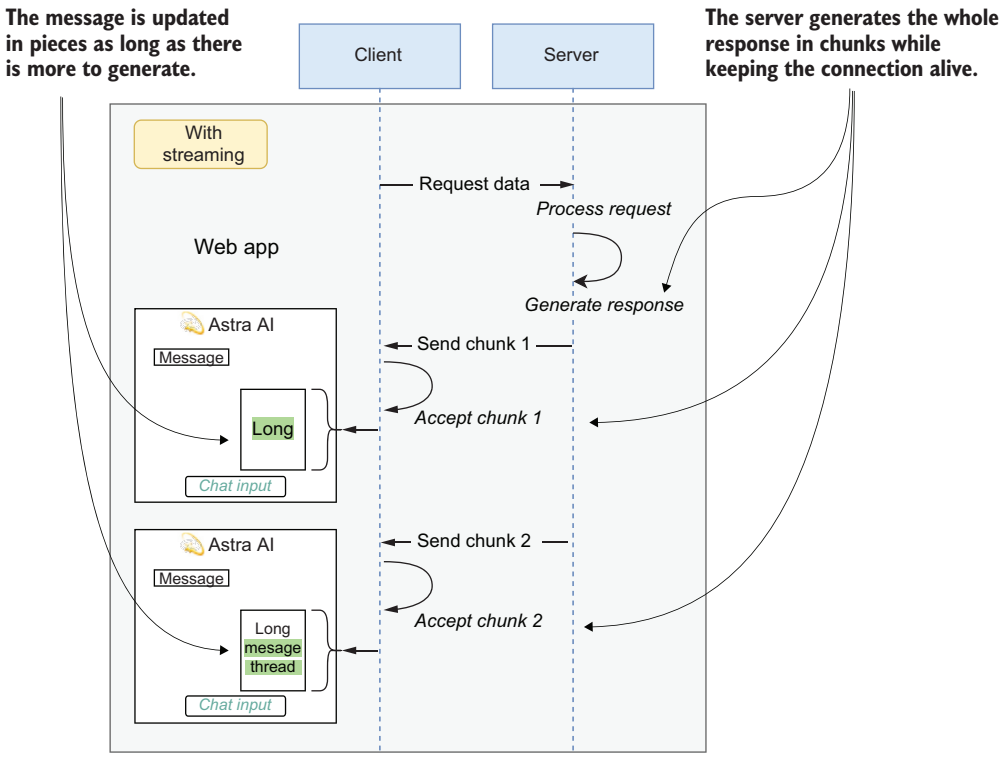

Figure 3.4 With streaming, the client sends a request, and the server sends the response in small chunks that are being streamed back to the client for processing.

3.2.2 Implementing streaming with the Vercel AI SDK

The Vercel AI SDK simplifies streaming with its `streamText` function and `useChat` and `useCompletion` React hooks. These tools handle the complex details of managing the stream and updating the UI, allowing you to focus on building your application.

STREAMING TEXT USING STREAMTEXT

The `streamText` function is the streaming counterpart to `generateText`. Instead of returning a full response, it provides an `async` iterable. You can loop over this iterable, processing each part of the text as it becomes available. The following listing shows an example of how to use `streamText`.

Listing 3.3 `streamText` example

```
import { createGoogleGenerativeAI } from '@ai-sdk/google';
import { streamText } from 'ai';

const model = createGoogleGenerativeAI({
  apiKey: process.env.GEMINI_API_KEY || '',
```

Imports the streamText function from the ai package. This function is used to stream text generations from a language model.
