`rep` is the type of value used to hold the internal representation of the `duration` object.

Std::Chrono::Duration::Period Typedef

This typedef is for an instantiation of the `std::ratio` class template that specifies the fraction of a second represented by the duration count. For example, if `period` is `std::ratio<1,50>`, a `duration` value with a `count()` of *N* represents *N* fiftieths of a second.

Declaration

```
typedef Period period;
```

Std::Chrono::Duration Default Constructor

Constructs a `std::chrono::duration` instance with a default value.

Declaration

```
constexpr duration() = default;
```

Effects

The internal value of the `duration` (of type `rep`) is default initialized.

Std::Chrono::Duration Converting Constructor From a Count Value

Constructs a `std::chrono::duration` instance with a specified count.

Declaration

```
template <class Rep2>
constexpr explicit duration(const Rep2& r);
```

Effects
