The internal value of the `duration` object is initialized with `static_cast<rep>(r)`.

Requirements

This constructor only participates in overload resolution if `Rep2` is implicitly convertible to `Rep` and either `Rep` is a floating point type or `Rep2` is *not* a floating point type.

Postcondition

```
this->count()==static_cast<rep>(r)
```

Std::Chrono::Duration Converting Constructor from Another Std::Ch- hrono::Duration Value

Constructs a `std::chrono::duration` instance by scaling the count value of another `std::chrono::duration` object.

Declaration

```
template <class Rep2, class Period2>
constexpr duration(const duration<Rep2,Period2>& d);
```

Effects

The internal value of the `duration` object is initialized with `duration_cast<duration<Rep,Period>>(d).count()`.

Requirements

This constructor only participates in overload resolution if `Rep` is a floating point type or `Rep2` is *not* a floating point type and `Period2` is a whole number multiple of `Period` (that is, `ratio_divide<Period2,Period>::den==1`). This avoids accidental truncation (and corresponding loss of precision) from storing a duration with small periods in a variable representing a duration with a longer period.
