

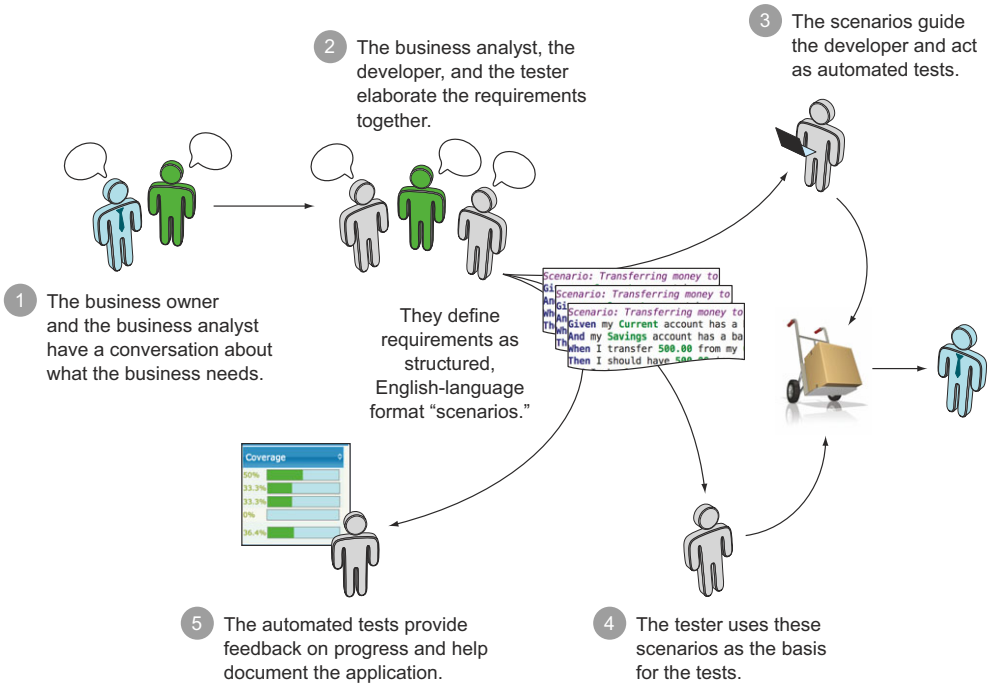

Figure 1.2 BDD uses conversations around examples, expressed In a form that can be easily automated, to reduce lost information and misunderstandings.

Chris's friend Sarah runs another company that just introduced BDD. In a team practicing BDD, the business analysts, developers, and testers collaborate to understand and define the requirements together (see figure 1.2). They use a common language that allows for an easy, less ambiguous path from end-user requirements to usable, automatable tests. These tests specify how the software should behave, and they guide the developers in building working software that focuses on features that really matter to the business.

1. Like Chris, Sarah talks to a business analyst about what she wants. To reduce the risk of misunderstandings and hidden assumptions, they talk through concrete examples of what the feature should do.
2. Before work starts on the feature, the business analyst gets together with the developer and tester who will be working on it, and they have a conversation about the feature. In this conversation, they discuss and translate key examples of how the feature should work into a set of requirements written in a structured, English-language format often referred to as Gherkin.
3. The developer uses a BDD tool to turn these requirements into a set of automated tests that run against the application code and help objectively determine when a feature is finished.
