The procedure for TS is summarized in Figure 5.13, where we use a *Sobol sequence* as the points that span the search space. We then draw a sample from the GP on these points and pick out the point that yields the highest value from the sample. This sample is then used to represent a sample from the GP itself, and the location at which the sampled value is maximized is where we will evaluate the objective function next.

IMPORTANT **Definition of a Sobol sequence**

A Sobol sequence is an infinite list of points in a region in Euclidean space that aims to cover the region evenly.
