

What about the output scale, then? We said earlier that this parameter scales the output of the covariance function to a different range. This is done by simply multiplying the covariance output with this parameter. Hence, a large output scale leads to the range of the GP's predictions being wider, while a small output scale shrinks this prediction range. To see that this is true, let's once again run our code and regenerate the predictions, this time setting the output scale to 3. Figure 3.12 is the produced output.
