```
  <li>Item 2</li>
  <li>Item 3</li>
</ul>
```

Instead of attaching a click listener to each `<li>`, attach a single listener to the parent `<ul>` element, as shown in listing 3.10. By using `event.target` and filtering logic within the event handler, only specific child elements (in this case, `<li>` items) will trigger the delegated event handler.

Listing 3.10 The click listener attached to the parent

```
document.getElementById('myList').addEventListener('click', funct
  if (e.target.tagName === 'LI') {
    console.log(`You clicked: ${e.target.textContent}`);
  }
});
```

Figure 3.1 illustrates event delegation, where an event listener is attached to a parent element (`<ul>`). When a click event occurs on any of the child elements, the event bubbles up to the parent element, triggering the event listener.

Figure 3.1 Event delegation pattern illustrated
