recruiter call focused on the candidate's background and work experience. Recruiters also verify legal work authorization, such as confirming visa status for non-immigrant candidates and whether the organization can sponsor an H1-B visa if needed. Salary expectations and compensation packages may be discussed to ensure alignment. While some companies still use quiz questions to assess basic knowledge, the prevalence of autograded online assessments or take-home projects has decreased compared to five years ago. Throughout the process, internal recruiters often remain available to answer questions and provide guidance.

Following the initial screening, candidates typically proceed to a screening interview. This stage normally involves a coding assessment led by the hiring manager or a technical interviewer. Candidates may be asked to implement algorithms, write JavaScript functions, or build simple user interfaces on a shared coding platform such as CodeSandbox. This step is crucial for assessing technical skills and problem-solving abilities. Depending on the company, candidates might also be asked questions to demonstrate their knowledge of the company or its products. Larger companies often have a larger pool of candidates, so it is common for candidates to explain why they are a strong fit, usually during the screening process or early on.

Successful candidates then move on to the full loop stage, a comprehensive evaluation that typically involves multiple interview rounds. This stage may take place on a single day or be spread across several sessions. It includes more in-depth coding assessments that build upon the initial screening. In recent frontend interviews, the focus has shifted away from algorithm-heavy, LeetCode-style questions toward project-based exercises, often conducted in a pair programming format. This approach enables interviewers to evaluate technical skills while observing how candidates collaborate and solve problems in real time.

For context, a typical LeetCode-style question might ask candidates to write an algorithm to find the Longest Increasing Subsequence (LIS) in a sequence (https://leetcode.com/problems/longest-increasing-subsequence/description). This problem requires identifying the longest subsequence in which the elements are in strictly increasing order. Such questions test not only the problem-solving ability but also the efficiency of the solution, with an
