With a foundation in memory management and code architecture, let’s dive into common interview questions to see how these concepts come into play.

Question: "What are ES modules in JavaScript?"

Analysis: This question evaluates a candidate’s understanding of modern JavaScript code organization and modularity. Interviewers use it to assess familiarity with the ES module system, its syntax (`import`/`export`), and its advantages over legacy module formats like CommonJS, AMD, UMD, and IIFE.

Answer: ES modules, introduced in ES2015, are the official standard for organizing and sharing JavaScript code across files. They enable splitting code into reusable modules with their own scope, using explicit `export` and `import` keywords. ES modules offer a cleaner, more maintainable alternative to older patterns and are widely supported in modern browsers and runtimes like Node.js.

ES modules have become more popular than other JavaScript module types, including:

- *CommonJS*—Used primarily in Node.js, relies on `require` and `module.exports` for synchronous imports and exports.
- *AMD (Asynchronous Module Definition)*—Designed for browsers, uses `define` and `require` for asynchronous loading to improve performance.
- *UMD (Universal Module Definition)*—A hybrid format combining AMD and CommonJS to work in both browser and Node.js environments.
- *IIFE (Immediately Invoked Function Expression)*—An older pattern to encapsulate code and avoid polluting the global scope, without standardized dependency management.
