To visualize re-renders, enable the "Highlight updates when components render" option, as shown in figure 4.11. This feature is accessible by clicking the gear icon in the Components tab and selecting it under the General settings.

Figure 4.11 Enabling the "Highlight updates when components render" option in React Developer Tools.

When enabled, components that re-render are highlighted with green borders, regardless of whether the cause is props, state, or context changes.

Alternatively, the Profiler tab within React Developer Tools—typically found alongside the Components tab (see figure 4.12)—offers a dedicated interface for in-depth performance analysis and tracking of re-renders. This essential tool enables developers to record profiling sessions, interact with the application, and then review detailed snapshots of each render cycle. These snapshots include key metrics such as render duration and the causes of updates, including changes to state or props. This granular information is invaluable for identifying performance bottlenecks, optimizing component rendering, and reducing unnecessary re-renders, ultimately leading to a smoother and more responsive user experience.
