```
    }
    return <h1>Something went wrong...</h1>;
  }
  return this.props.children;
}
```

`react-error-boundary` (https://github.com/bvaughn/react-error-boundary) is also a popular third-party library that provides a robust and flexible Error Boundary component. It is a lightweight solution that simplifies error handling in React applications, building upon React's native Error Boundaries feature and introducing modern methods using functional components and hooks. This library is widely used for managing runtime errors gracefully, ensuring applications remain stable and user-friendly.

An application can implement multiple Error Boundaries, which allows for independent error handling in distinct parts of the application. This strategy increases the granularity of error management, providing more control over how errors are caught and displayed. Nesting Error Boundaries adds another layer of error handling. If an inner Error Boundary fails, the error can propagate to a parent Error Boundary. Even components within `<React.StrictMode>` can be wrapped with Error Boundaries (listing A.11). This facilitates error handling in a more fine-grained manner, even when using Strict Mode to enforce best practices.

Listing A.11 App component wrapped with Error Boundary inside React.StrictMode

```
const App: React.FC = () => {
  return (
    <React.StrictMode>
      <ErrorBoundary>
        {/* Application code */}
      </ErrorBoundary>
    </React.StrictMode>
  );
};
```

NOTE

Error boundaries also have limitations, as detailed in the official React documentation.
