readers and enhances SEO by clearly signaling the most important section of the page.

- `<article>` represents a self-contained piece of content that could stand alone, such as a blog post. Wrapping the content in an `<article>` helps both browsers and search engines understand that this block is a distinct, meaningful unit. This structure is particularly beneficial for SEO, as search engines can better index and present the article as a relevant result.
- `<header>`, placed within an `<article>`, contains introductory content—such as the web page title or article name—grouped together at the top of the article. This approach not only mirrors the logical structure of most documents but also aids screen readers in quickly summarizing the content's context. In addition, it improves code clarity and makes the markup easier to maintain for future updates.
- `<section>`, placed within an `<article>`, defines a section that contains thematically related content. This helps organize the content and provides a clear structure for the article. It allows assistive technologies to navigate content more efficiently and enhances SEO by helping search engines better understand the relationships and hierarchy of the content.
- `<footer>`, parallel to `<main>`, represents the footer section of the page, containing information such as copyright notices, contact details, or links to related content. It supports SEO by providing additional context and navigation options for search engines.

The `<main>` element and its associated semantic elements are defined in listing 2.2.

Listing 2.2 The BlogPost <main> element defined using semantic elements

```
<main>
  <article>
    <header>
      <h1>{post.title}</h1>
      <h2>{post.subtitle}</h2>
    </header>
    {post.sections.map((section, index) => (
    <section key="{index}">
      <h3>{section.title}</h3>
```
