```
      {section.subsections.map((subsection, subIndex) => (
      <div key="{subIndex}">
        <h4>{subsection.title}</h4>
        <p>{subsection.content}</p>
      </div>
        ))}
    </section>
    ))}
  </article>
</main>
```

Jane used React code to demonstrate the use of HTML semantic elements. She also highlighted an important feature introduced in React 19: native support for metadata tags. When React renders a component like `BlogPost`, it recognizes tags such as `<title>`, `<link>`, and `<meta>` within the component and automatically hoists them to the `<head>` section of the document, as illustrated in figure 2.3 (inspection output). Hoisting means React moves these metadata tags from anywhere in the component tree to the document's `<head>`, ensuring proper placement for SEO and accessibility. This eliminates the need for third-party libraries or manual metadata management.

Figure 2.3 Generated HTML code showing <title>, <link>, and <meta> tags hoisted to the <head> section.
