```
  children: React.ReactNode;
  id: string;
}
const Button: React.FC<ButtonProps> = ({ children, id }) => (
  <button className="button primary-button" id={id}>
    {children}
  </button>
);
const CssSpecificityExample = () => (
  <div className="container">
    <style>{styles}</style>
    <Button id="my-button">Click me</Button>
  </div>
);
```

Instead of rushing, she clarified the scope by asking: "Are we evaluating the background color, text color, or border color?" This demonstrated her attention to detail and understanding of component styling nuances.

Here is her analysis:

- *Text color*—`#my-button` (ID selector, specificity 1-0-0) overrides `.primary-button` (class, 0-1-0) and `button` (element, 0-0-1). The result is yellow (`color: yellow`).
- *Background color*—`.container .primary-button` (two classes, 0-2-0) beat `.primary-button` (0-1-0) and button (0-0-1). The result is green (`background-color: green`).
- *Border color*—No explicit border styles are defined, so it defaults to `border: none`. If a border existed, its color would likely be black.

Jane explained the CSS hierarchy using her annotated figure 2.7.
