maintainability. If time permits, it is beneficial to mention how the codebase could be further optimized in a real-world scenario, such as by setting up build tools for minification or auditing unused CSS. There are a few techniques to achieve the performance enhancement that are summarized in table 2.2.

Table 2.2 CSS performance optimization techniques

Technique	Description	Benefit
Minify and compress	Use build tools (CSSNano, UglifyCSS, plugins) or online tools to remove whitespace and comments; enable Gzip or Brotli compression on your web server.	Smaller file sizes, faster loads
Combine files	Merge multiple CSS files into one using build tools or scripts to reduce the number of HTTP requests.	Fewer requests, quicker rendering
Browser caching	Configure the web server to set appropriate cache headers (e.g., Cache-Control) for CSS files.	Reduced repeat downloads
Simplify selectors	Use efficient, less specific selectors (prefer single classes, avoid deep nesting and IDs) in CSS.	Faster CSS parsing
Remove unused CSS	Use browser DevTools coverage panels, Chrome extensions, code editor extensions, standalone tools (PurifyCSS, UnCSS), or online services to audit and	Less CSS to process
