efficient management of device resources.

Answer: To use the camera in a web application, the standard approach is to use the `navigator.mediaDevices.getUserMedia()` API, which enables direct access to the device's camera and microphone from the browser. First, check if the browser supports this API. If support is available, request user permission by calling `getUserMedia` with appropriate constraints, such as `{ video: true }` for video only or `{ video: true, audio: true }` for both video and audio. The resulting media stream can then be assigned to the `srcObject` property of a `<video>` element to display the live camera feed within the application.

When discussing camera integration in a web application during an interview, it is important to demonstrate awareness of several key considerations. First, the Camera API only works on secure origins, such as HTTPS, localhost, or file URLs, which is essential for protecting user privacy and security. Not all browsers or devices support this API, so feature detection and providing graceful fallbacks are necessary to ensure broad compatibility. Permissions and privacy are critical: always request user permission, handle cases where access is denied, and clearly communicate the reason for requesting camera access to build user trust. For devices with multiple cameras, such as front and rear cameras on smartphones, use the `navigator.mediaDevices.enumerateDevices()` method to list available cameras, and present a selection interface to the user. Test across multiple browsers and devices to ensure consistent behavior and fallback options for unsupported features. Error handling should be implemented to address scenarios like denied permissions, unavailable devices, or unsupported browsers. Additionally, consider the impact on device resources and strive to provide a responsive, accessible user interface for a positive user experience.

While it may be uncommon to fully implement camera functionality during an interview, thoroughly discussing these details demonstrates the ability to deliver a secure, user-friendly, and cross-browser compatible camera integration in web applications. This level of understanding reflects strong technical competence and a thoughtful approach to real-world development challenges.
