- *Client-side validation*—Added `validateName` and `validateEmail` functions for thorough checks, including regex pattern matching. The validation functions are included in a separate file, `form/utils.ts`, for improved readability and maintainability.
- *Improved state management*—Initial state now includes a "fields" object for form input values, ensuring consistent state.
- *Form field enhancements*—Removed "required" and "pattern" attributes; used `defaultValue` instead, populated from `state.fields`.
- *Error handling*—Client-side validation errors are handled before API calls, with specific error messages.
- *CSS classes*—Error and success messages now have "error" and "success" CSS classes for easier styling.
- *Modular code structure*—Separate validation functions improve readability and maintainability.

Listing 2.9 Advanced form implementation

```
const Form: React.FC = () => {
  const [state, formAction, isPending] = useActionState<FormState
    async (prevState, formData: FormData) => {
      const name = formData.get('name') as string; #A
      const email = formData.get('email') as string; #B
      const nameError = validateName(name); #C
      if (nameError) { #D
        return {
          data: null,
          error: nameError,
          fields: {
            name,
            email,
          },
        };
      }
      const emailError = validateEmail(email);  #E
      if (emailError) {
        return {
          data: null,
          error: emailError,
          fields: {
            name,
            email,
          },
        };
```
