and you should see comments and reviews be at least double the value of the number of pull requests, as you saw in figure 4.17.

Figure 4.17. Pull requests charted with pull request comments

One thing to note is that figure 4.17 is aggregating data every sprint. That means you're seeing the total pull requests and the total comments after the sprint period (usually two to three weeks) is complete. If you're practicing Kanban and/or tracking these stats with greater granularity, then another trend you might want to look for is the difference between when pull requests are open, when comments are added, and when commits are finalized. Ideally you want pull requests to be committed soon after they're submitted. If for some reason you see the trend shown in figure 4.18, you may have an issue.

Figure 4.18. Commits and comments lagging behind pull requests is usually a bad pattern.
