Once you have the relevant data points, you can always stop there and track the individual data. This might work for some people, but it's useful to have a single data point that allows you to keep a bird's-eye view on groups of data without having to micromanage every data point. This will also lead to much cleaner, more succinct dashboards that can be shared outside the team and make more sense at a glance.

Now it's time to do a bit of math. If we stick with the examples shown in figures 7.11 and 7.12, we have several data points that we can roll up to give us an indication on how good our team's estimates are. We want to know at a glance if the team is over- or underestimating and by how much. If we visualize the association of estimates to time, we'll see something like figure 7.13.

Figure 7.13. A visual representation of a series of estimates next to time using the Fibonacci series of estimates over a two-week period

First, we'll name our metric to track estimation accuracy. Let's call this one estimate health. Estimate health is some combination of the following data points:

- Estimates
- Task start time
- Task end time
- Amount of work
