releases, and a low number of fixes. This ultimately shows that your code is maintainable enough to easily make small tweaks and get in front of the consumer quickly.

Let's look at an example. A team is practicing CD and releasing updates to their consumers three times a day. They keep track of their CLOC for each release, as shown in figure 8.8, which includes a month's worth of hot-fix release data. Based on their target, is their code base maintainable?

Figure 8.8. The amount of code that changes for all hot fixes in a month

Figure 8.8 shows the following statistics over the course of a month with 60 releases made by the CD system:

- Ten commits were made and different hotfixes were deployed.
- Of those ten commits, on average only six lines of code were added and four were removed.
- Therefore 16% (10 in 60) of the total releases were hot fixes.

If you assume that the CD system makes 3 releases in an 8-hour day with about 3 hours between releases, then the following are true:

- For the 10 releases that needed to be fixed, for about 30 hours in the month (out of 730 total hours in a month) the code was in a state that needed to be fixed.
