

Overall the architecture is pretty simple. You'll use jobs to schedule the collection of data, services to parse individual data sources, and domain objects to represent each type of data you want to index. Grails has the following out-of-the-box capabilities to help you set up these components:

- Create jobs with just a few lines of code.
- Create simple objects usually called plain old Groovy objects (POGOs) that use Grails Object Relational Mapping (GORM) to handle interaction with the database.
- Create services that you can autowire into other classes with a single line of code.

Because the Grails framework takes care of the tedious plumbing that would go into making the previous things work in other languages, you're free to focus on getting the data you want from the source systems without having to focus on only making things work.

A note on using other languages and frameworks

Over the last several years I've built a few different versions of this application. The first rendition used Python instead of Grails. I ended up switching to Grails because I prefer working in it. It runs on the JVM, which made it easy to get up and running on the infrastructure I had
