The development team was now using data visualization in different ways to shape how they operated, and they were able to turn this into real-time data that the leadership team could peek at whenever they wanted.

2.5. Building on the system and improving their processes

After showing how just a few pieces of data can give better insight into the application lifecycle, the development team decided to start pulling even more data into the system, expanding the set of reports it could generate. They were looking at how well their system was performing through their log analysis, and they were measuring team performance through their PTS and SCM systems. One of the main outcomes they wanted to effect by improving their velocity was to improve the time it took to deliver changes that improved the application to their consumers. To see how their deployment schedule correlated with their project tracking, they decided to add release data into the mix. Getting CI and deployment data was the next logical step, as highlighted in figure 2.13.

Figure 2.13. By adding data from the build and deployment system, the development team was able to add release dates to their analysis to track how changes they made to their process affected delivery time.

Because they used their CI system to release code, they could pull build information from their deploy job and add releases to their analysis. Upon doing that, their dashboard started to look like the one shown in figure 2.14.

Figure 2.14. Adding releases to the dashboard. Now the team can see how their process affects the speed at which they release code.
