The recommender then scrapes a website showcasing new movies and appends that information to a new prompt request to an LLM. With this information, the LLM responds to the recommender, which passes this back to ChatGPT. ChatGPT then responds to the user with the recommended request.

We can think of plugins as proxies for actions. A plugin generally encapsulates one or more abilities, such as calling an API or scraping a website. Actions, therefore, are extensions of plugins—they give a plugin its abilities.

AI agents can be considered plugins and consumers of plugins, tools, skills, and other agents. Adding skills, functions, and tools to an agent/plugin allows it to execute well-defined actions—figure 5.2 highlights where agent actions occur and their interaction with LLMs and other systems.
