We can now look at the code for the `scoring` and `aggregate` blocks, starting with the scoring code in listing 9.3. This scoring code averages the score for each criterion into an average score. The output of the function is a list of processed recommendations.

Listing 9.3 `line_process.py`

```
@tool
def line_process(recommendations: str):     #1
    inputs = recommendations
    output = []
    for data_dict in inputs:                      #2
        total_score = 0
        score_count = 0

        for key, value in data_dict.items():     #2
                if key != "title":     #3
                    try:
                        total_score += float(value)
                        score_count += 1
                        data_dict[key] = float(value)     #4
                    except:
                        pass

        avg_score = total_score / score_count if score_count > 0 else 0

        data_dict["avg_score"] = round(avg_score, 2)    #5
        output.append(data_dict)

    return output
```

#1 A set of three recommendations is input into the function.
#2 Loops over each recommendation and criterion
#3 Title isn't a criterion, so ignore it.
#4 Totals the score for all criteria and sets the float value to key
#5 Adds the average score as a grounding score of the recommendation

From the grounded recommendations, we can move on to aggregating the scores with the `aggregate` block—the code for the `aggregate` block is shown in the following listing.
