- Agent profiles and personas guide an agent’s tasks, responses, and other nuances, often including background and demographics.
- Actions and tools for agents can be manually generated, recalled from memory, or follow predefined plans.
- Agents use knowledge and memory structures to optimize context and minimize token usage via various formats, from documents to embeddings.
- Reasoning and evaluation systems enable agents to think through problems and assess solutions using prompting patterns such as zero-shot, one-shot, and few-shot.
- Planning/feedback components organize tasks to achieve goals using single-path or multipath reasoning and integrating environmental and human feedback.
- The rise of AI agents has introduced a new software development paradigm, shifting from traditional to natural language–based AI interfaces.
- Understanding the progression and interaction of these tools helps develop agent systems, whether single, multiple, or autonomous.
