```
    features = data['features']

    # Make prediction
    prediction = model.predict([features]).tolist() # Return prediction as JSON
    return jsonify({'prediction': prediction}) except Exception as e:
    return jsonify({'error': str(e)}), 400

if __name__ == '__main__':
    app.run(debug=True)
```

Key Features of the Code:

1. **Model Loading**: The pre-trained model is loaded using joblib.load, ensuring consistency with the training pipeline.
2. **API Route**: A POST endpoint (/predict) is defined to handle prediction requests.
3. **Input Handling**: The API parses input features from JSON data sent in the request body.
4. **Error Handling**: Basic error handling is implemented to return meaningful messages for invalid inputs or issues.
5. **Flask Development Server**: The app runs on a local development server with debugging enabled.

Steps to Deploy the Flask API

1. **Prepare the Model**:
    - Train your machine learning model using libraries like scikit-learn, TensorFlow, or PyTorch.
    - Save the trained model using joblib or pickle to ensure compatibility during deployment.
2. **Set Up Flask**:
    - Install Flask using pip:
    - pip install flask
    - Create a Python script with defined API routes and endpoints.
3. **Test Locally**:
    - Run the Flask app locally to test API functionality:
    - python app.py
