3.1.3 Sending messages back and forth: Adapting responses

The manager is responsible for creating one worker per text to be parsed and sending the worker the text. Sending a message from the manager to the worker works the same as before, but now the worker must reply to the manager. This is where a new concept comes into play: the adapter.

An adapter is needed for the worker's response because the response type belongs to the worker, not the manager. The worker uses its own protocol to respond, and that is a problem. Remember that each actor has its own protocol. That is the only protocol it understands, so in principle, the manager cannot understand the worker's answer.

For the manager to understand the worker's answer, you need two things: an adapter function and an adapter message. The adapter function is used to send a message to the worker, and the adapter message is used to receive a message from the worker.

The rest of the process—creating a worker—is the same as with the guardian. Spawning is all you need.

The manager consists of four parts:

- A message adapter in the protocol
- An adapter function
- Delegating (creating a worker per text and sending the text for parsing)
- Receiving the worker's response and logging its task completion
