```
  final case class Delegate(forms: List[String]) extends Command
  private final case class WorkerDoneAdapter(response: Worker.Response)
      extends Command

  ...
}
```

It is worth noting that the modifier is `private`. This ensures that no actor other than the manager uses the message. Otherwise, the manager could receive this message from any actor confirming that a text has been parsed. Only the manager can convert a `Worker.Response` message into a `WorkerDoneAdapter` message.

3.1.5 The adapter's function

The adapter's function is an actor (an `ActorRef`) that lives between two worlds. It is an `ActorRef[Worker.Response]`, so it is a `Worker.Response` sharing the protocol of the worker (shown in the next section). It understands the worker responses. On the other hand, the adapter has a reference to the manager. And since the adapter's function has the worker protocol and the manager's reference, it can act as their intermediary:

```
object Manager {
  ...

  val adapter: ActorRef[Worker.Response] =
        context.messageAdapter(rsp => WorkerDoneAdapter(rsp))    ❶
}
```

❶ .messageAdapter belongs to the context API (ActorContext).

The manager sends a request to the worker, and the worker responds to the adapter, which in turn wraps the worker's message
