```
  ...

  def ask(target: ... createRequest: ...)(implicit responseTimeout:
  ➥Timeout): Unit

  ...
}
```

Scala implicits

Scala implicits are a difficult subject. For now, here is a TL;DR version that is sufficient for you to understand this example.

To fill implicit arguments like `responseTimeout`, Scala looks for compatible types marked as `implicit val`. The compiler looks for these values in the same class—among other places—and if it finds them, it uses them as input for the implicit arguments. And that's it; implicit arguments can be automatically filled with implicit values that appear in the same class.

Therefore, it is enough to add the timeout in this class as an implicit value for the `ask` to be populated. The compiler determines that the timeout is the right argument for the `ask` method and uses it.

To repeat, `Worker.Parse` can be used in the manager as `context.ask(worker, Worker.Parse)`. Even if the signature is `Worker.Parse(replyTo: ActorRef[Worker.Response])`, you don't need to add the parameter `replyTo` when instantiating a `Worker.Parse`. This parameter is created and added for you by the `ActorSystem` and acts as the intermediate actor, just like the adapter in the previous section. When you put all these pieces together, you get the following manager.

Listing 3.4 Manager that asks
