```
          replyTo ! Worker.Done                                          ❺
          Behaviors.same
      }
    }

  private def fakeLengthyParsing(file: String): Unit = {
    val endTime = System.currentTimeMillis + Random.between(2000, 4000)
    while (endTime > System.currentTimeMillis) {}
  }
}
```

❶ Protocol

❷ Text to parse

❸ Fake reading of the delegated task

❹ Prints a message including the actor's name

❺ Replies to whatever is asked

Now you have the whole picture and the details of this application for parsing text implemented with `ask`.

3.2.6 Using context

So far, you've seen how an actor can `log`, `ask`, `spawn`, and refer to itself using `context`. Using `self` is handy when you want to use the actor's path. You may remember from chapter 2 that the path is formed by the hierarchy of an actor's parents and children. Here is the path of one of the workers:

```
akka://example-ask-without-content/user/manager-1/worker-file-c#-1664156553
```

Before you move on to the next example, you need to understand how `ask` works under the covers if you want to use it when you send a message with a payload—for example, if you send the worker the message to parse along with the `replyTo`.
