NOTE You should not pay much attention to the `implicit classTag`. It is there for historical reasons and binary compatibility.

Now let's move on to the most common use of `ask`, which is a little different from what you've seen so far. There are two ways to use `ask`: the empty one you just saw, where the message sent as a question contains only a `replyTo`, and the loaded one, where the message sent contains additional information.

In the next section, you change your parsing worker; and instead of passing the text to be parsed when you create the worker, you pass the text in the message sent to the worker each time you ask it to parse. This way, the worker can process a different text each time.

3.3 Ask with a payload

To include the text to parse in the message, the protocol of the worker must be as follows:

```
object Worker {

  sealed trait Command
  final case class Parse(
        text: String,                          ❶
        replyTo: ActorRef[Worker.Response])
    extends Command

  sealed trait Response
  final case object Done extends Response

  ...
}
```

❶ Provides the text to parse
