- Traditional Akka applications are built as a hierarchy of actors. The first actor is the `ActorSystem`, and below it are its children. The children created by the `ActorSystem` can create other children, and so on, creating the hierarchy of actors.
- When you send messages back and forth between two actors, you need the adapters to convert the response to the protocol of the receiving actor.
- You can create adapters with `context.messageAdapter`.
- Instead of `tell`, which is fire and forget, an actor can ask. The asking actor expects an answer within a certain time. Therefore, it must specify a timeout and a callback handling both cases: the possible `Success` and `Failure`.
- You can use currying in a function like `sum(Int: a, Int: b)` with `sum(Int: a)(Int: b)`. Currying allows you to create more complex adapters that you can use with `ask`.
