spawned, has been stopped, or has no effect yet. There are about a dozen types of `akka.actor.testkit.typed .Effect` (see http://mng.bz/WAl1). Let's test `Spawned` and `NoEffect`.

Here you have the same scenario as in the previous chapter where you created workers from the manager so they can parse a text. For simplicity, let's look at the parts that show you how to test an effect: in this case, the creation of the worker.

This simplified scenario has two actors, one creating the other. One of the actors—the worker—is of type `String` and ignores all messages it receives. Similar to `Behavior.same`, `Behaviors.ignore` provides the `ignore` function. This is the actor's protocol:

```
object SimplifiedWorker {
   def apply() = Behaviors.ignore[String]
}
```

The next actor protocol—the manager—is as follows:

```
object SimplifiedManager {

  sealed trait Command
  final case class CreateChild(name: String) extends Command

  ...
}
```

This actor creates a `SimplifiedWorker` for each `CreateChild` message:

```
object SimplifiedManager {

   ...                                                    ❶
```
