```
            Behaviors.same
}
```

How can you prove that the simplified manager forwards the message? To prove this, you need `TestInbox[T]`. With it, you create a probe that is a fake actor—here, a fake worker—and a queue where it keeps received messages (its inbox). The idea is to test whether the forwarding works by examining the probe's inbox and seeing if the forwarded message is there. You check this with `probe.expectMessage(message: T)`.

NOTE This method consumes the message from the inbox. Each time you call `probe.expectMessage(message: T)`, a message—if any—is fetched and removed from the probe's inbox.

The test is as follows:

```
class SyncTestingSpec ...

  ...

  "actor gets forwarded message from manager" in {
     val testKit = BehaviorTestKit(SimplifiedManager())
     val probe = TestInbox[String]()                              ❶
     testKit.run(SimplifiedManager.Forward("hello", probe.ref))
     probe.expectMessage("hello")                                 ❷
  }

  ...
}
```

❶ Probe with a stubbed actor ref and a queue as an inbox

❷ Asserting could poll messages from the queue.

4.2.3 Testing the logs
