Logging is an essential part of any program, and as such, it is included in the manager/workers parsing application from the previous chapter. With the `BehaviorTestKit`, you can check whether logging works as expected. The underlying mechanism is the same as for effects or messages. The logs are stored in a queue, and you can retrieve them to check your expectations.

Let's use the same `SimplifiedManager` actor as in the previous examples and add logging, first to the protocol and then to the actor:

```
object SimplifiedManager {

    sealed trait Command                          ❶
    case object Log extends Command               ❶
    ...

    def apply(): Behaviors.Receive[Command] =
      Behaviors.receive { (context, message) =>
        message match {
              ...
          case Log =>
            context.log.info(s"it's done")        ❷
            Behaviors.same
        }
      }
  }
```

❶ Protocol

❷ Logging

You need to know two things to check the logging:

- The log entries are accessible via `testKit.logEntries`.
- These entries are wrapped in the `CapturedLogEvent(level: Level, message: String)` class.
